De la dépendance des cellules des êtres vivants à la biologie moléculaire, la "souffrance des êtres vivants" peut être un concept complexe à analyser.

La biologie moléculaire est une branche de la biologie qui étudie les processus cellulaires à l'échelle moléculaire. Elle a permis de comprendre de nombreux aspects des êtres humains et des animaux, y compris comment ils fonctionnent à l'échelle de la cellule.

La "souffrance des êtres vivants" est un concept qui a été discuté dans le contexte de la biologie moléculaire, mais il est également important de considérer comment les êtres vivants peuvent être soufferts dans d'autres contextes, tels que la médecine ou l'écologie.

En conclusion, la biologie moléculaire a apporté de nombreux avantages en termes de compréhension des êtres vivants, mais elle est également important de considérer les aspects éthiques et moraux qui y sont liés, y compris le concept de la "souffrance des êtres vivants".

Blanching
Spinach leaf midribs
Quantification
Nitrate

Leelawadee UI Semilight
Although nitrates, are sometimes favorable to health, they can however convert to nitrosamines inside the body thanks to the acidic medium of gastrointestinal tract. So, the investigation of the nitrate content in food products becomes an imperative since it allows consumers to choose their food deliberately.
The leaching kinetics of nitrates during water blanching of spinach leaf midribs (SLM) was investigated at different conditions of time and temperature.
The nitrate leaching kinetics during the water blanching of SLM samples was studied at 60, 70 and 80 °C; for 3 and 15 minutes. Presently, six models, namely Henderson and Pabis, logarithmic, zero order, Lewis, Page, Wang...
Furthermore, to elucidate the effect of the temperature on the nitrate diffusion rate, the equation of Arrhenius was applied. Results showed that after 15 min of blanching, the removal rate (RR) of nitrates was of: 23.851±3.477c,

\[ (p \leq 0.05) \]

and Singh were tested to analyze experimental data. Moreover, to elucidate the effect of the temperature on the nitrate diffusion rate, the equation of Arrhenius was applied. Results showed that after 15 min of blanching, the removal rate (RR) of nitrates was of: 23.851±3.477c,

\[ (p \leq 0.05) \]
activation energy (35.76 kJ)

...the six tested models, the logarithmic model seemed to be the most appropriate (R²=0.993) to describe the...
Conclusions:

Based on the rate constant appearing in the most appropriate model.
an effective tool for controlling the nitrate content in vegetables, by varying the time and
temperature of treatment.
The European Food Safety Authority (EFSA, 2010) has alerted about the possible existence of methemoglobinemia.
overconsumption (>1 portion a day) in children, due to of spinach.

The spinach leaf midribs (SLM), including petioles, represent the plant material used to investigate the leaching kinetics of nitrates during blanching in water.
It has been reported that the petioles removal is known to be a way through which nitrates accumulate about 40% of all nitrates assimilated by the whole plant.

It has been reported that the petioles removal is known to be a way through which nitrates accumulate about 40% of all nitrates assimilated by the whole plant. It has been reported that the petioles removal is known to be a way through which nitrates accumulate about 40% of all nitrates assimilated by the whole plant. 15) to analyze experimental data related to the kinetic of nitrate leaching during water blanching of SLM. These models are those applied by Doymaz and Ismail [1] to investigate water removal during drying of sweet cherry and they are normally resulting by simplifying the general series solution of Fick’s second law. Lewis, Henderson...
and Page models are widely used to describe water diffusion in most biological materials [29]. Considering that the investigation of nitrate leaching can be considered as an extraction procedure [13] and that the extraction curves show a similar shape to that of the sorption curves [30], it becomes possible to use the same mathematical models for describing the leaching kinetics of nitrates. The latter authors have employed Page and logarithmic models to analyze the process of solid-liquid extraction of polyphenols from soybeans. Studying the evolution of antiradical capacity with treat

ment.

Suh et al. [3] found that the zero-order kinetic model describes more adequacy experimental data.

Quispe-Fuentes et al. [3] communicated that among several applied models, the modified Henderson and Pabis model presents the best fit quality regarding the leaching process of saponins from quinoa (Chenopodium quinoa Willd.) seeds during washing with water.

Finally, experimental data related to the kinetics and temperature dependent moisture diffusivities of Pumpkin seeds during drying were fitted into four thin-layer drying models including Lewis as well as Wang and Singh models [3].

Furthermore, to elucidate the effect of the temperature on the diffusion rate, the Arrhenius equation was applied (01):

\[ k = k_0 \exp \left( \frac{-E}{RT} \right) \]

where, \( k = \) diffusion rate, min \(^{-1}\), \( k_0 = \) pre-exponential constant, min \(^{-1}\), \( E = \) activation energy, kJ.mol \(^{-1}\), \( R = 8.314 \times 10^3 \) kJ.mol \(^{-1}\) K \(^{-1}\), and \( T = \) temperature.

Nitrate determination procedure was performed using the spectrophotometric procedure described by Golubev [3] and improved by Aoun et al.
Fifty (50) g of representative sample was homogenized with distilled water for 30 min in volumetric flask (500ml). After homogenization, the suspension was allowed to stand for 1 hour with periodic mixing. The volume was then brought to the mark (at 500 ml) with the distilled water before being mixed and filtered. Then, 50 ml of the filtrate was acidified with 4 ml of acetic acid (2%) until pH 4. The solution was then evaporated until dry using Rotavapor (BUCHI Switzerland). The obtained residue was solubilized with a small quantity of distilled water, and the new solution obtained was filtered in a volumetric flask at 100 ml. The filtrate was supplemented with 5 ml of saturated NaCl solution and the volume was finally brought to the mark with distilled water.

Four (4) ml of Diphenylamine reagent was added to 1 ml of final extract (using glass cells with optical path lengths of 1 cm). The absorbance was measured with spectrophotometer (spectrophotometer UV-VIS/ JASCO V-530) at 590 nm. The nitrate content is deduced from a calibration curve which was traced using standard solutions (0.015, 0.030, 0.045, 0.075, and 0.150 mg KNO$_3$/ ml) according to the procedure reported by Aoun et al.

The Diphenylamine reagent was prepared by adding slowly 90 ml of concentrated sulfuric acid (98%) to 10 ml of distilled water, avoiding stirring. After that, the solution was added progressively and in small amounts to 0.5 g of Diphenylamine, according to the method described by Bartzatt and Donigan, and Aoun et al.

Statistical analysis
All statistical analyses were performed
using the STATISTICA program (Version 5.5). The results were expressed as mean ± SD, and a one-way analysis of variance (ANOVA) was performed. In all data analysis, a value of p≤0.05, p≤0.01 and p≤0.001 were the signification levels tested. All tests were performed in triplicate (n=3).

The Minitab software (Version 15) was used to elucidate the modeling of the kinetics of nitrates leaching during blanching at different temperatures.

Results

The calibration plot of nitrate concentration, as a function of absorbance (not presented here), was found to be linear in the concentration range studied (up to 0.150 mg KNO$_3$/ml, with $R^2$ = 0.991), whereas the initial nitrate content of SLM is of (3860 ± 1.789) mg/kg.

Figure 1 shows the concentration variation of nitrates SLM during their blanching in water at different temperatures. As it can be observed, the nitrate content decreases over the blanching process whatever the temperature.

However, the decrease rate dramatically increases when the temperature varies from 60 to 70°C, after which the nitrate rate diffusion takes place slowly.

Figure 1:
Variation of nitrate concentration in Spinach leaf midribs during blanching at different temperatures.

From these results, are deduced removal rates (RR) of nitrate [RR = 1 - (C$_{15}$/C$_0$)]; where C$_0$ and C$_{15}$ concentrations of nitrates in spinach stalks at t = 0 and after 15 min of blanching, respectively. Rates obtained at three different temperatures are displayed by the histogram on figure 2. It can be observed that the RR value at 80°C (75.949±5.366a) %, is the highest, followed by that obtained at 70°C (64.809±0.474b) %, with significant differences (p≤0.05) observed. In contrast, the RR at 60 °C was four times lower than RR 80°C (p < 0.05).

Figure 2:
Removal rate (RR) of nitrates versus blanching temperature of spinach leaf midribs after 15 minutes. The Same letters indicate the absence of significant differences (p ≤ 0.05) between values.

Generally, the curve of figure 3 shows an inverse shape compared to that of figure 1 that show that the nitrate concentration in blanching water varied with time and temperature of heat treatment. It is comprised between (213...
167 ± 21 mg/l at 60 °C

after 3 minutes of treatment

and (1473.333 ± 103.545) mg/l after 15 min at 80 °C

The nitrates content

in the bleaching water, deduced after 15 minutes of bleaching at 60 °C was

three times lower than

that obtained at the highest values of time and temperature.

Figure 3:

Variation of the nitrate content in the blanching water as a function of time and temperature.

Similarly, the results on Figure 4, show that the recovery rate (RRt)

= C

15

/C

0

) of nitrates in the bleaching water, after 15 minutes of treatment, was

considerably influenced by the treatment temperature: 12.120±1.734c, 32.599±0.234b

and 38.169±2.682a % at 60, 70, and 80 °C, respectively.

A significant difference was observed (p < 0.05).

Figure 4:

Recovery rate (RRt)

of nitrates in the blanching water, after 15 min of treatment at different temperatures. The Same letters indicate the absence of significant differences (p ≤ 0.05) between values.

Table 1 summarizes the results related to the modeling of the leaching of nitrates during water blanching of SLM. The most important information contained in these data concerns the appropriateness of the logarithmic model, provided the value of the coefficient of determination (R

2

≥ 0.993) at 70 and 80 °C, as well as the good correlation between the values predicted by the model and those found experimentally (Figure 5).

Figure 5:

Correlation curves between the experimental values and the values predicted by the logarithmic model at different temperatures.

(a)

(b)

(c)
Figure 6 displays the effect of temperature on rate constant corresponding to the selected model. The straight slope allows to deduce the activation energy (35.76 kJ mol⁻¹) associated with the transfer of nitrates (from the food matrix to the blanching water).

Discussion

The maximum level nitrates concentrations limited by the European Union (EU Commission Regulation No 1258/2011 2 December 2011) is of (3500 mg/Kg). Spinach, this popular leaf vegetable, known to be rich in various essential nutrients, is however susceptible to contain considerable amounts of nitrates [37, 40]. Furthermore, it is known that the nitrate content is heterogeneously distributed in vegetable organs according the following descending order: petiole > leaf > stem > root [15]. At the same time, the petiole and midrib of wild plants present generally the similar nitrate content which is on the other hand higher than that of lamina [14], which are consistent with the value of the initial nitrate content in SLM deduced before bleaching. We suppose that the more or less superposition of the curves at 70 and 80 °C for both cases of SLM (Figure 1) and blanching water (Figure 3) indicates that the temperature of 70°C could be considered as critical in terms of destroying action on the tissue structure of the plant involving de facto subsequently an easy release of nitrate molecules from the food matrix. In fact, studying the nitrate extraction of nitrates during blanching of spinach, Graiser et al. [37] reported that at temperatures lower than 57 °C, the cell membranes are impermeable to ionic substances such as nitrates and there was a unique slight difference in leaching rates between 80 and 90 °C. The RR results (Figure 2) are consistent with those found by other authors concerning the blanching of various products: potatoes peeled, cut into halves and blanched in water at 75 °C for 20 min: 21% [41]; leaves of Hibiscus sabdariffa boiled for 10 min: 73% [42]; amaranthus (Amaranthus cruentus) leaves boiled for 10 min: 64% [43]; leaves of...
Corchorus olitorius cooked for 10 min: 88%.

Enemo et al. [44] revealed that, after 15 min of blanching (at 100 °C) of some edible plants of Niger, the rate of loss of ascorbic acid was over 90%. On the other hand, Chavarri et al. [4, 5] noticed that the washing and blanching of five fruits and green vegetables, including spinach, leads to the elimination of more than 50% of pesticides. As illustrated on Figure 4, the recovery rate (RRt) of nitrates, in the bleaching water after 15 minutes, was considerably increased exceeding 60 at 80 °C; those that justified the nitrate concentrations that lose SLM are recovered by the bleaching water. Those results are in agreement with those obtained by Graiser et al. [13].

In addition, from the results illustrated on Figure 2 and Figure 4, we observe that, whatever the blanching temperature, the recovery rate of nitrates, in the bleaching water, was equal to almost half of the removal rate (RRt ≈ 0.5 × RR); which explains the instability of nitrates during water bleaching, and, that a significant part of the nitrates disappeared.

This interesting element is to consider. At first glance, two principal causes may explain the instability of nitrates: a) enzyme activity which has not been inhibited during heating treatment, knowing that nitrates are susceptible to the Nitrate Reductase activity [4, 6]; and b) their interactions with other components of reaction medium (ex. carbohydrates, vitamins, amino acids, etc.), knowing that, glucose and ascorbic acid being considered as the most predisposed molecules to
react with nitrate in certain conditions, including high temperatures [47, 48]. This nitrates instability is supported by Ismail et al. [49] who found that time and temperature stimulate considerably the oxidoreduction reactions of nitrates in blanched Amaranthus (leafy vegetable).

Results from Table 1 and Figure 5 are in concordance with those described in the literature. Thus, among the six models used for modeling the drying kinetics of apple slices, Rayaguru and Routray [50] showed that the logarithmic model is more appropriate.

On the other hand, as has already been pointed out, only two studies have examined the effect of blanching on the nitrate content. Unfortunately, the kinetic modeling was not taken into consideration. It must be noticed that food blanching can, at the same time, induce other undesirable changes such as loss of water-soluble vitamins that needs to be considered for a better optimizing of the blanching process.

The value of the activation energy (35.76 kJ mol⁻¹) associated to the transfer of nitrates from the food matrix to the blanching water was two times lower than that found (74 kJ mol⁻¹) by Varoquaux et al. [23, 24] concerning the loss of nitrate during carrots blanching. This difference could be explained by the structural nature of the two types of tissues and the difference in physicochemical composition of the two plant matrices, being that some chemical substances can influence the result of nitrate diffusion kinetics during the bleaching process [47, 48].

Conclusions
Our results showed that water bleaching is an effective technological operation to regulate nitrate levels in vegetables before consumption. It is worth emphasizing that nitrates are the source of nitrites as a result of their reduction in the body [51].
Therefore, we consider interesting in terms of prevention to quantify nitrates in foods before consumption in order to act on them by various treatments. Indeed, it has already been reported that the nitrate content in spinach is often 250 times higher than that of nitrates.

Furthermore, the removal rate of nitrates depends on the temperature of the heat treatment that it is three times higher at temperature 80 °C compared with the result obtained at 60 °C. In addition, the time of bleaching was significantly influencing the loss of nitrates.

The modeling results indicate that the Logarithmic model is the most appropriate ($R^2 > 0.993$) model for deducing the transfer energy of the nitrate ions in the food matrix to the bleaching water whatever the treatment temperature.

It would certainly possible to improve the treatment, taking into account other parameters such as the size of the plant pieces, the solid phase (food matrix / blanching water ratio), and the loss of numerous valuable nutrients (vitamins, some minerals, amino acids, etc.).
